Hybrid Cloud: The Pragmatic Path to Infrastructure Modernization

Prashant K. Prasad

Regional Sales Director and Client Partner, USA

ABSTRACT

Businesses turn to the hybrid cloud model to combine their on-site infrastructure with public cloud to revamp their operational footprint. The research focuses on or benefits the proliferation of operational flexibility, scalability, cost and business efficiency necessary for those processes that must keep running in a hybrid cloud. This study has been approached using quantitative data collection technique with IT Professionals of different business industry sectors. The results indicated that 89% of respondents felt more flexible on the operation and 84% of respondents felt the greatest benefit to be on the side of cost optimisation. 88% of the participants cited security and data privacy as a challenge to them. The study revealed that organizations stepped up their automated provisioning from 28% to 76%, once they introduced hybrid cloud systems. The study revealed that using hybrid cloud will enable organizations to modernise infrastructure without facing significant operational risks, while offering a sustainable approach to the modern infrastructure.

Keywords: Hybrid Cloud, Cloud Computing, Infrastructure Modernization, Digital Transformation, Infrastructure as Code (IaC).

DOI: 10.21590/ijhit.02.02.01

I. INTRODUCTION

In the mid-1900s, companies were faced with pressures to upgrade their systems to meet their businesses' need for improved agility, operational efficiency and flexibility of systems. As business requirements proliferated, and technology was integrated into the infrastructure systems, managing the systems became increasingly difficult. Despite the demand for a public cloud, many companies lacked both security concerns and compliance requirements, and struggled with the reliance on legacy applications. Organizations needed to find an efficient solution to the situation which led them to use of hybrid cloud. The research paper demonstrates how hybrid cloud systems can update the infrastructure by integrating private cloud solutions with public cloud resources. The study looks at how automation, governance, workload management and operational flexibility are effective in hybrid cloud deployments.

II. RELATED WORKS

Hybrid Cloud Adoption

Cloud Computing is as an essential technology for enterprises as it provides flexible computing resources that could be accessed over the web. Cloud platforms adoption started with the need to increase operational efficiency and decrease costs, and improve the organization's ability to react to market needs. Most companies trying to move their entire applications to public cloud solutions faced security concerns and compliance constraints and were unable to make it work in the current systems. There were two reasons for developing a hybrid cloud system—a need to integrate with private cloud systems and the need to connect to public cloud systems.

Research has shown that hybrid could enable organizations to make gradual changes to their systems, instead of carrying out a full system replacement. Research indicates that enterprises preferred hybrid approach as it allowed them to have sensitive applications in their private data centers and less-sensitive workloads in the public cloud and benefit from its scalability [1]. The approach helped organizations maintain their needs and requirements while enjoying new cloud-based innovations. Large enterprises saw the hybrid cloud as one of the major ways to do business in long term measure.

The predominant reason behind an organization's decision to use hybrid cloud technology is the desire to shift the workload between the different environments. Organizations need not migrate everything to the public cloud services.

Customers and organizations that relied on legacy systems, continued to operate using on-premise systems while moving their customer-facing and operational systems to the cloud [10]. Through the process of control modernisation, the organisations could empower their efficiency in fulfilling control activities without having to discard necessary business functions.

Hybrid cloud strategies emerged as organizations began to acknowledge cost savings. The first step of cloud technology gave birth to the misconception that all organisations can always save money with public cloud services. Not planning workload needs and not optimizing the operations resulted in increased cloud costs for organizations [10]. With the hybrid cloud solution, enterprises could assign their workloads depending on the number of times they used their systems. Businesses can put their stable operations into private systems and make use of public clouds for shifting operational requirements. Previous work on multi-tier partitioning in hybrid cloud environments demonstrated that proper placement methods could reduce the operational costs and improve application response time [10].

Business continuity and resilience is important to assist the hybrid cloud adoption process. A need was identified to function using different infrastructures where they're not relying on a single provider or physical data centre. Studies on hybrid cloud resiliency frameworks demonstrated that hybrid cloud frameworks enhanced the disaster recovery and continuity of services by distributing service workloads in between cloud environments [4]. Many sectors, like banking, healthcare and manufacturing, found this flexibility a necessity as any downtime would cause a loss of significant operations and finances.

Data-driven distribution and hybrid computing environments were studies with Supercloud computing [3]. This "Supercloud" concept resulted in a user driven design and allowed it to provide organizations control over their services across multiple private and public cloud systems without an undue reliance on a single vendor. The study proved that today's needs in enterprises need to include both interoperability requirements and portability as priority. The objective can be achieved by keeping flexibility in the operation and modernization of the infrastructure.

Security, Governance, and Management Challenges

The hybrid cloud system provides multiple advantages to users, but research reveals major difficulties which organizations experience when they handle their distributed infrastructure systems. The research studies show that security represents the most common issue which people discuss in their security research. Enterprises adopting hybrid cloud architectures must manage workloads, data, and applications across both private and public environments, which increases complexity and creates additional security risks [1].

In a systematic literature review, the security concern was identified as one of the critical challenges faced by the organizations in the adoption of public cloud [1]. The fear of regulatory compliance issues, data breaches and lack of control over sensitive business data in public cloud environments was the reason enterprises were hesitant to move the data into the cloud. With stringent data protection laws, other sectors like healthcare and finance sectors had to bear an extra burden. The organisations generally wanted to continue to keep their critical systems on their own infrastructure while enjoying limited access to public cloud services.

Several different studies came up with "Management Complexity" as one of the major challenges that should be overcome by organizations. The hybrid cloud environment presents administration challenges as the admins have to deal with various platforms, providers and technologies as opposed to traditional cloud infrastructure which is much easier to manage [1]. Process deficiencies resulted in operational disruptions as enterprises' separate tools made it difficult for their employees to gain access to a unified operational information. Combined with the many different cloud vendors, organizations required strong governance that would allow them to work with different systems and procedures in order to deal with the workload.

A few studies on Service Level Agreements (SLAs) revealed that the management of the cloud service is more complicated. Organisations have been using different cloud services which has posed problems to them when they had to manually check the SLA documents. SLAs specify the service availability, terms of service performance, penalties and responsibilities of the service provider and service customer. The study suggested a way to improve cloud service management with automated techniques with the Semantic Web and Text Mining (TWM) approaches [2]. The research revealed the need for governance automation to maximize enterprises' control over distributed infrastructure through continuous monitoring and enforcing policies in a hybrid cloud environment.

Interoperability emerged as the main challenge for organizations adopting hybrid cloud systems. Operational models, interfaces and technologies are different in the cloud and pose a challenge for integration [3]. Problems arise due to lack of standardization and the lack of cooperation between services. However, supercloud research was introduced to solve this issue by proposing some architectures to specialize the interoperability and reduce the reliance on vendors [3]. The research highlighted the need for portability of cloud service in future cloud strategies and for cloud service to have unified management.

The literature mentions another problem, which confirms the requirement of service-systems to continue functioning in case of failure and in disaster scenarios. A complexity in operation of the hybrid environments is to support the hybrid work load that will require multiple services with different location. In some researches, ontological-based resiliency frameworks were developed that found ways to discover services and be recovered when a system fails [4]. In this context, ontology technologies were used to design unified cloud service description systems that facilitated the process of resource selection in the case when a system outage occurs. The research shows that organizations can rely on smart technology systems to smooth the business operations across dispersed work environments.

Operations in the different applications in the cloud results in various operational issues. For migration processes, the traditional solutions mainly focussed to migrate virtual machines and transfer data and ignoring the relationships of workloads and requirements of network systems [9]. Researchers built sophisticated models to plan migration which allows an organisation to distribute the load among their networks optimally, taking into consideration the actual network connections and evaluating how effective their infrastructure is for migrations [9]. A successful hybrid cloud migration involves proper planning processes along with the creation of governance structures and workload capacity evaluations.

Automation and Architectural Transformation

As hybrid infrastructures got more complicated, businesses had to go all the way to implement the automation solutions, a need that was crucial to successful infrastructure modernization. Numerous studies indicate a need for a new method of managing distributed and dynamic cloud environments. Organizations are increasingly embracing automation to increase their efficiency. They want improved scalability and being able to seamlessly operate from their hybrid infrastructure basis.

The study of autonomous self-adaptive cloud architectures showed that the system's ability to make decisions and the management processes used to monitor its operation during runtime are crucial elements for its successful operation [6]. A set of analytical models was developed to evaluate the architectural tactics dynamically and establish the stability in the case of maintaining QoS (Quality of Service) [6]. It demonstrates how businesses can benefit from automation technology, increase their management of hybrid clouds and still maintain a moderate manual management level.

It became imperative to have tools that enabled infrastructure automation as part of enterprises' modernization efforts. The use of Infrastructure as Code (IaC), configuration management systems and automated provisioning systems were adopted early in many organisations, allowing for more consistent processes to be deployed, and reducing time to task implementing the tools. Several studies have been published that an automatic management system can provide significant benefit for a faster provisioning [6].

Service-oriented architecture (SOA), and agile and iterative program development techniques were also helpful in integrating with hybrid cloud modernization initiatives [5]. It was revealed that a company needs to implement systems that would allow it to run continuous integration and incremental service deployment. The study presented architectural models that support the automatic integration and deployment functions for services in the cloud. This hybrid cloud management field shows an overall trend moving towards DevOps and agile working methods.

Architectural flexibility became relevant in the industry in adopting the advanced cyber systems and cloud supported operations. The HORSE manufacturing project investigated the potential of a hybrid cloud setup for human-robot-cooperation and human cloud systems, showing that it is an excellent option for collaboration between human operators, robot arsenal and cloud-based management platform [7]. One of the main findings of the research was that the Cloud-based systems allowed for simpler installation processes as well as better scalability. This research shows that hybrid cloud isn't just a technology that is changing the way of IT operations, but also the way manufacturing and industrial operations are changing.

UAV and wireless sensor network architectures utilized an intelligent and distributed architecture which showed the ability of hybrid cloud [8]. The solution would be based on software defined networking (SDN) together with network function virtualization (NFV) and cloud orchestration to make the infrastructure more flexible [8]. The study reveals that hybrid clouds can accommodate new technologies, as they reduce hardware dependency from the centralized control systems that they're built on.

The task of optimizing the workload for migration and deployment processes proved to be an important subject for research. Enterprises started to require intelligent workload placement techniques that required consideration of both their network and infrastructure requirements [9]. Using automated optimization models was seen as a way to reduce the amount of resources used while merging various servers, and lower the migration cost for organisations [9].

III. METHODOLOGY

The research adopts quantitative research methods to investigate the relation of the function of the modernizations of infrastructure that can be achieved by using hybrid cloud systems in big organizations. The study looks at five critical business areas that are impacted by adopting a hybrid cloud - operational flexibility, cost optimisation, business continuity, governance efficiency and automation. The research should be carried out using quantitative approach to ensure that the researchers could collect measurable data from enterprise IT professionals that can help them to draw patterns or trends and study the relationship between different variables that relate to hybrid cloud adoption.

The study has been informed by the actual experience of industry with the implementation of hybrid cloud transformation programs, especially in large organisations, and their own complex infrastructure environments. The findings also concur with the literature on hybrid cloud, which speaks of a progressive resolution of the conflict between on-premise infrastructure and the cloud service.

The study will take a look at a group of IT managers, cloud architects and infrastructure engineers and DevOps and technology professionals in enterprises that have implemented or are in the process of implementing a hybrid cloud strategy. Organizations within the banking, financial services, healthcare, manufacturing and retail sectors are studied primarily since these sectors frequently experience problems with their infrastructures from the regulatory, security and operational angles when upgrading to modern facilities. Participants will be selected using purposive sampling approach with specific regard to their experiences and knowledge of hybrid cloud and/or infrastructure programme for modernization.

The data to be collected is going to be from a structured questionnaire survey. It will be an enclosed question set asking for the responses on a 5-point scale from "Strongly Disagree" to "Strongly Agree". The survey questions will evaluate users' assessment of hybrid cloud adoption benefits, security concerns and governance effectiveness and automation in use, and their ability to manage workloads and reporting on their overall hybrid cloud experiences. There are also demographic questions included in the questionnaire, asking people about the type of industry they work in, organization size and job role as well as their experience of cloud technologies (length of time).

Workload portability, automation adoption, IT governance practices and security management are some of the independent variables in this study. Effectiveness of infrastructure modernization is considered as dependent variable. The study aims to validate that those organizations that have better infrastructure automation capabilities, along with stronger governance and efficient workload distribution strategies, will be able to successfully modernize their applications and services across the infrastructure via their hybrid cloud deployments. During analysis phase, these variables will need to be analyzed to see if there is a statistical relationship between them.

All the information collected will be assessed using a statistical approach. Descriptive statistics (Percentages, mean score and Frequency distribution) will be used to convey their responses. To examine the relationship between the various factors of hybrid cloud and the results of infrastructure modernization, correlation and regression analysis will be used in the study. Whether automation and governance become significant enablers to improve operational flexibility and realize modernization achievements will be evaluated with the help of the techniques.

The survey will use the academic literature and industry practices that are used to define hybrid cloud computing to design the survey questions. Pilot test with a small number of respondents is also carried out to check unclear questions and to change the structure of the questionnaire. The procedure of research would meet ethical demands for conducting the research. Participants in the survey will complete the survey at their choice while their answers will be kept secret.

IV. RESULTS

Enterprise Adoption Patterns

Businesses are using hybrid clouds as their preferred choice of infrastructure for infrastructure modernization. The majority of respondents agreed that hybrid cloud offered a good balance between their on-premise infrastructure and capabilities in the public cloud. Organizations indicated that hybrid cloud will help them move forward in digital transformation.

The majority of study participants reported that their companies implemented hybrid cloud solutions because they needed to address security issues and compliance obligations and maintain their existing applications. Organizations with their entire environment on public cloud hosting experienced operational risks and didn't accelerate their migration to cloud due to their current system environments. Organizations were implementing hybrid cloud solutions to deploy and update targeted business processes while proactively moving their core processes out without disruption.

Banking, healthcare and manufacturing industries were more likely to adopt hybrid cloud than smaller less regulated industries. Regulatory requirements and concerns over data privacy weighed heavily in their decision-making process

for the type of infrastructure they selected for the sectors that responded. By building reliable public cloud applications for customers while maintaining private cloud services for their critical information, organizations have been able to keep sensitive information within a private environment.

Table 1: Industry Distribution

Industry Sector	Number of Respondents	Percentage (%)
Banking & Financial Services	42	28%
Healthcare	26	17%
Manufacturing	31	21%
Retail & E-commerce	22	15%
IT & Technology Services	18	12%
Others	11	7%

The results showed that workload-based placement served as the primary factor which drove organizations to adopt hybrid cloud systems. The organizations chose not to change their regular and compliance-driven workloads since they were going to run their dynamic workloads in the public cloud. The strategy helped organisations to attain greater operational agility and flexibility while retaining their current risk management frameworks. Most of those who had used hybrid cloud systems felt that they were able to take a step-by-step incremental upgrade approach to their infrastructure, which they believed carried less risk than the standard big migration.

Another significant discovery was that business continuity or disaster recovery management were integral components of an organization's operational activities. As companies deployed their applications in one or more environments instead of a single infrastructure provider, they reported better resilience. The respondents reported improved service availabilities and continuity upon implementing hybrid cloud solutions.

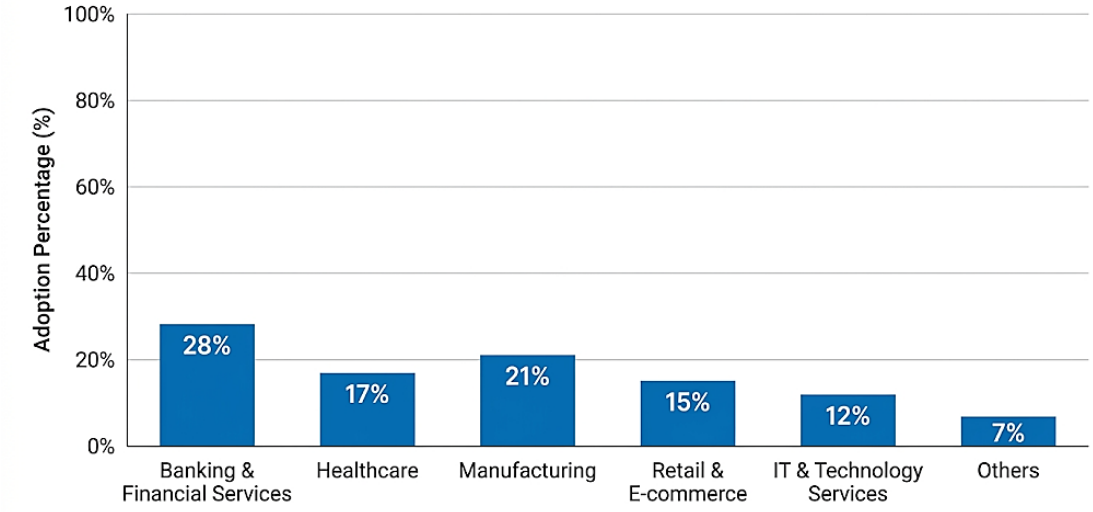

Fig. 1: Industry-wise Hybrid Cloud Adoption Rate

The study findings indicate that hybrid cloud was indeed a viable upgrade option since it met the existing actual working requirements of organizations. The organizations intended to transform in any way that would enable them to continue with their businesses while fulfilling their growth and innovation goals.

Cost Optimization and Operational Efficiency

Based on the findings of the research, hybrid cloud technology offered benefits in terms of cost control and operational efficiency that were advantageous to a number of companies. Respondents noted that the hybrid environments allowed organizations to share their workloads based on three criteria: performance needs, capacity of infrastructure, and business priority. To optimize costs, enterprises scaled their operations between the greatest cloud platforms and their own data centers, rather than moving their workloads to the cloud.

When asked why hybrid cloud solutions are so popular, the survey results indicated that cost optimization is among the top reasons for the popularity of hybrid clouds. Organizations found a few workload applications were not saving money with public cloud services. Organizations looking to manage predictable workloads and have consistent overall resource needs found that a private data center was a more cost-effective solution. The public cloud platforms could offer businesses the scale of their resources when required, with variable workloads.

Table 2: Key Benefits Reported

Benefit Factor	Mean Score (Out of 5)	Agreement Percentage (%)
Operational Flexibility	4.5	89%
Cost Optimization	4.3	84%
Improved Scalability	4.4	87%
Business Continuity	4.2	81%
Better Resource Utilization	4.1	79%

The research results showed that businesses achieved better infrastructure utilization results after they adopted hybrid cloud solutions. It helped organizations to utilize hardware resources with optimum efficiency while eliminating unnecessary usage of hardware and enhancing the scalability of applications. The respondents reported faster provisioning of resources in a hybrid cloud environment, and that it reduced the delays that had been felt when deploying using traditional infrastructure methods.

The second important finding related to automation throughout the study. The participants stated that automation technologies have helped them save some repetitive administrative tasks and achieve repeatability across the infrastructure systems. Various persons emphasized that implementing automation has results in improved service delivery due to speed of operations. The system enabled organizations to finish tasks which previously needed multiple days or weeks within a few hours through its automated deployment and provisioning capabilities. The new operating system improved greatly in productivity and reduced human errors for infrastructure management.

Table 3: Operational Improvements

Operational Area	Before Adoption (%)	After Adoption (%)
Automated Provisioning Usage	28%	76%
Infrastructure Visibility	34%	71%
Resource Utilization Efficiency	41%	78%
Faster Deployment Capability	37%	82%
Reduced Downtime Incidents	46%	69%

The findings revealed that companies that were successful at addressing hybrid cloud complexity challenges had employed some form of automation. Those organizations that adopted automation by enacting policies and having a centralized governance structure realized greater operational efficiency and better infrastructure management. The evidence shows that automation is a key technology that helps organizations move toward expansion of their hybrid cloud system with modern ways of working.

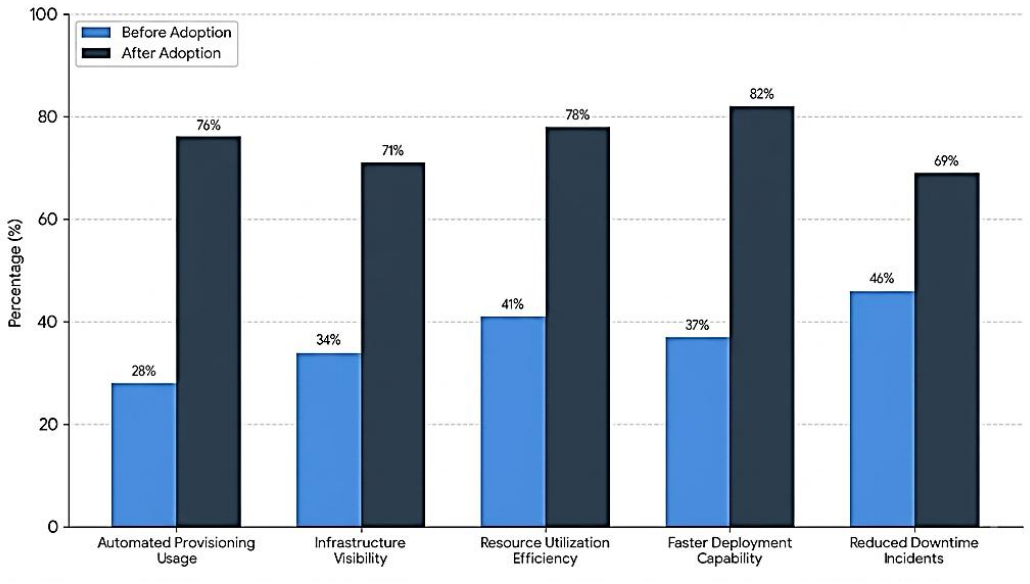

Fig. 2: Comparison of Operational Efficiency

Security, Governance, and Infrastructure

The research has found organizations that have implemented hybrid cloud solutions had positive outcomes but have faced significant challenges during the implementation process and day-to-day usage. The most common issue among participants in the study was security issues. Public cloud providers faced significant challenges in providing security for their sensitive data in environments with multiple infrastructure types.

The primary need identified by the respondents was compliance needs and regulatory requirements in banking and healthcare services. The industries required full control of their customer information and access points and over their systems as a whole. Hybrid models were selected by enterprises for two reasons: first to preserve their critical systems within the enterprise's private environment, second to access public cloud resources for non-critical business functions.

The findings of the research showed dramatic increase in governance complexity in hybrid environments. Organizations encountered challenges because they were required to manage several tools, working differently and having their full lifecycle processes invisible across various systems. The use of many tools to run separate environment of infrastructure created hindrances in the operation, thus contributing to the slow decision-making process as explained by the respondents.

Table 4: Challenges in Hybrid Cloud Implementation

Challenge Area	**Respondents Reporting Challenge (%)**
Security & Data Privacy	88%
Governance Complexity	81%
Integration Issues	76%
Limited Infrastructure Visibility	69%
Skill Gaps in Cloud Management	63%
Vendor Interoperability Problems	58%

The analysis revealed organisations face difficulty with digital change in the early phases of the process when they have a hard time with process changes as well as technology. The level of complexity in integration was among one of the main issues recognized in the study that organizations require to deal with. Integrating old systems with new cloud-based ones is challenging for organizations. Older applications proved themselves tied to traditional infrastructure and not able to be integrated with cloud-native applications. If the respondents' reasons for delays are correct, integration issues caused extra infrastructure spending, which is where the action taken to implement the business rule took place.

The study concluded that there is a widespread need for organizations to have core competences that are missing. Most of the businesses needed to have an experienced workforce that would be able to manage their hybrid cloud setup. There was a challenge set for everyone to allow their infrastructure teams the opportunity to learn cloud management and automation tools and DevOps practices. According to the respondents, cultural resistance, as well as a working methodology operating in silos, presented challenges that hindered modernization programs.

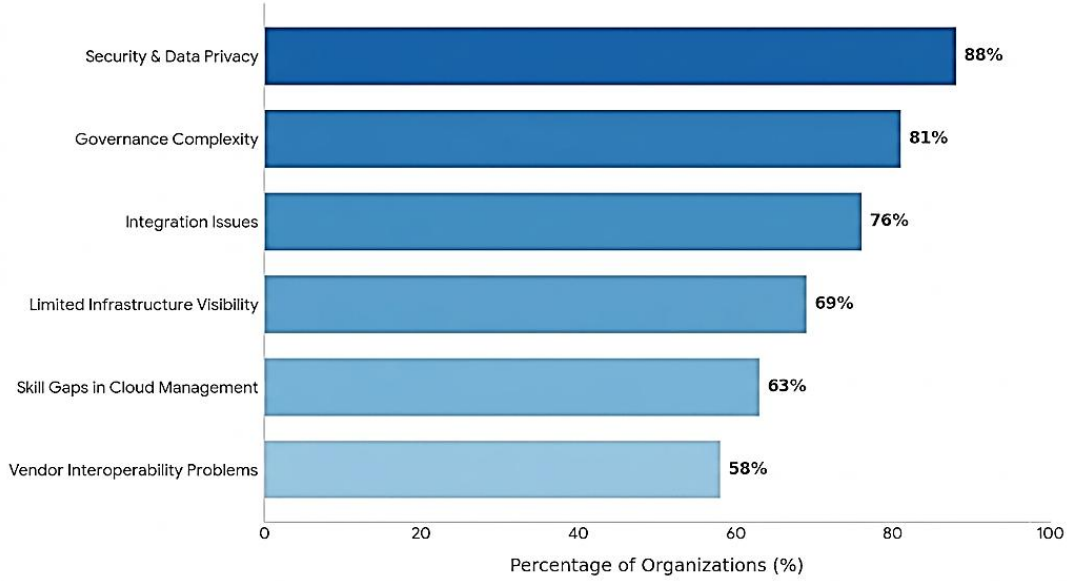

Fig. 3: Major Challenges in Hybrid Cloud Adoption

Organizational Transformation

The findings presented in the study showed that adoptions of hybrid cloud were a combination of a technological change and an organizational transformation. Organizations knew that they must also embrace new operational model adjustments along with updates to governance models and team working processes in order to achieve effective infrastructure modernization.

The study revealed that a hybrid cloud solution had a positive impact on collaboration and synergy between teams of application and infrastructure teams and business units. Organizations had to shift their ways of operating due to the distributed cloud environment demands. Organizations implemented DevOps practices together with centralized governance frameworks to enhance their operational coordination and efficiency.

The results revealed that the organisations that adopted a phased modernization approach performed better than those companies that attempted a comprehensive modernization effort in a short time. The respondents emphasized the need for organizing a balance between creation and continuation of the business. The groups that adopted gradual migration strategies in their modernization initiatives reported less disruption in operations and their teams were more effective in handling work activities.

Another major finding from the research was that an action plan for strategic planning needed to be formulated. Most respondents feel hybrid cloud is a way to get to cloud, rather than going through it as a transition or on-going solution. The prime reason enterprises adopt the hybrid cloud as their primary approach is to manage various tasks related to businesses and meet the varying operational demands.

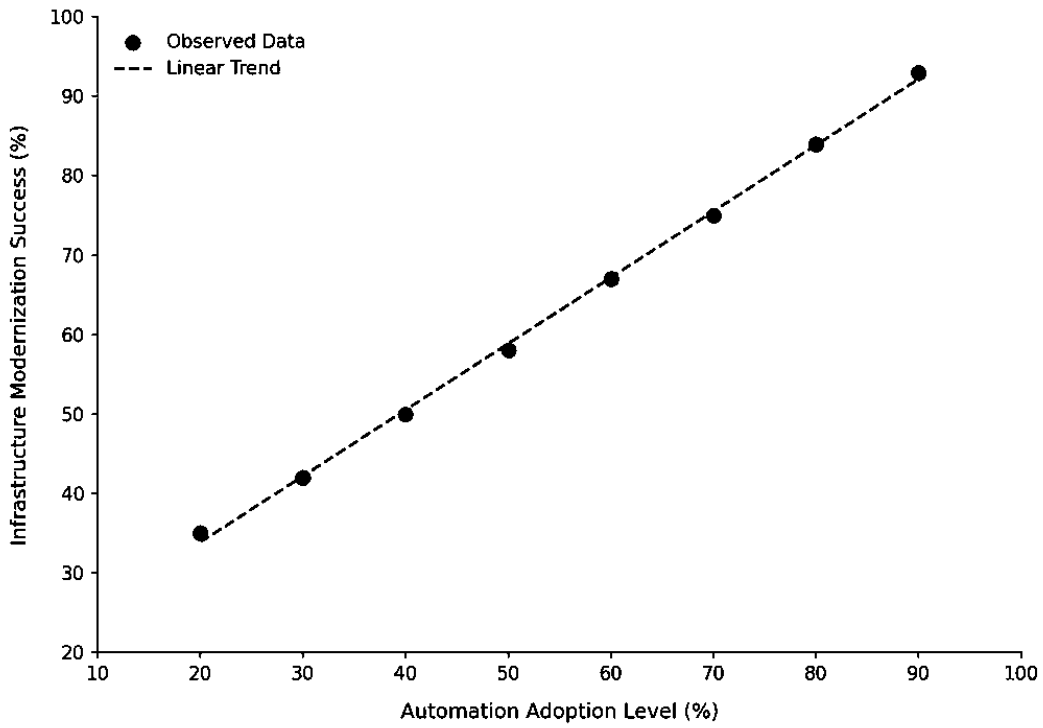

Fig. 4: Automation Adoption and Modernization Success

V. CONCLUSION

The results indicate that organisations embraced hybrid clouds to best balance innovation and operational stability, and to mitigate migration risk. Advantages for enterprises implementing hybrid cloud solution included improved operational flexibility and more scalability, as well as resource utilization, and flexibility with business operations. The research identified three main security issues and two main challenges regarding the complex governance requirements and difficulties in integrating existing systems. The study found that augmenting with centralized control systems that help to optimize hybrid cloud operations is the key to improved operational performance for organizations using automation. A hybrid cloud solution serves organizations as a stepping stone in the process of transforming their infrastructure, offers a way for organizations to keep managing and being adaptable while delivering sustainable results in terms of performance.
